#### A Search Criteria

The first step in our systematic review consisted in gathering a study sample. We started our data collection with a manual search based on a set of keywords we scouted from the distributive politics literature. This search produced a database with many entries that were unrelated to our subject of investigation. To reduce the number of false positives in our sample, we restricted our search to studies that cited Weingast, Shepsle and Johnsen's 1981 paper "The Political Economy of Benefits and Costs: A Neoclassical Approach to Distributive Politics", which is a seminal contribution in the field. Although Google Scholar reports the article amounts to 2,180 citations<sup>1</sup>, our search resulted in 2,664 records as of the 21<sup>st</sup> of November 2019.

We webscraped three large academic databases: Google Scholar (n = 1001); Microsoft Academic (n = 927); and Scopus (n = 736). The R script we wrote extracted the article title, abstract, authors, year, journal of publication, and database from which the record originated. Our code is available in section K.2 below. We screened these results with an English language and article restriction, that is, we excluded all records written in other languages and all that were not academic papers, such as book chapters or doctoral theses. To reduce the risk of publication bias, we set no restriction to unpublished articles.

## **B** Article Selection

The selection process was conducted by two authors in three stages. In the first round, we excluded all titles that were obviously unrelated to our topic. For instance, we curiously found articles about automobile motors amidst our sample. We consider this a preliminary step, since we were not able to eliminate a large number of entries. Then, we read all abstracts. We chose to maintain those which indicated that either government expenditure or legislative structures were the main subject of the paper. For instance, if the paper sought to identify variables that increased government size, it was maintained. Abstracts that indicated the paper discussed or estimated the impacts of representative institutions, elections, or chamber dynamics were also included. This allowed us to significantly reduce our sample to 376 records.

In the second phase, we assessed full texts. To remain in our sample, the paper should (i) conduct a quantitative analysis, (ii) report data on the number of legislators, and (iii) also on public expenditure. If the record was marked as positive for all three, it was maintained. Disagreements in this phase were discussed among the authors, and a third investigator was consulted when needed.

<sup>&</sup>lt;sup>1</sup>As of May 11<sup>th</sup>, 2020.

The third phase consisted of filling out tables for each of the remaining 50 articles to systematically evaluate

their eligibility. Since authors use different measures for government spending and the number of lower/upper

house members, we extracted all coefficients that provided this information. We decided which variables

to keep by following the current practices of the literature. In this phase, we also collected information on

whether or not the paper had been published, and if it explicitly discussed the *law of 1/n*. Upon choosing the

variables, we excluded the non-conforming studies, arriving at our final sample of 26 articles.

**B.1** Exclusion Analysis

We selected the final pool of articles based on two criteria regarding their reported coefficients:

1. Matched treatment variable:

• *N*: Number Legislators in the Lower House

• logN: Log Number Legislators in the Lower House

• *K*: Number Legislators in the Upper House

2. Matched outcome variable:

• ExpPC: Expenditure Per Capita

• logExpPC: Log Expenditure Per Capita

• PCTGDP: Percent GDP Public Expenditure

**B.2** Flow Chart

The diagram below shows each step of our article selection process. We followed the Preferred Reporting

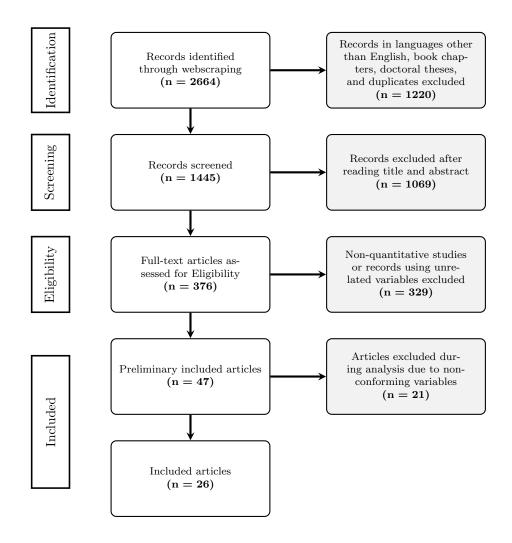

Items for Systematic Reviews and Meta-Analyses (PRISMA) statement to conduct our study<sup>2</sup>. The column to

the right depicts the amount of articles excluded in each phase, and the one to the left shows the number of

records evaluated.

<sup>2</sup>More information about the PRISMA statement is available at http://www.prisma-statement.org.

4

# **B.3** Study Sample

A table with the 26 selected articles is available below. It includes information on the article author, the journal in which the paper was published, the publication year, the country of analysis, the level of data aggregation, and whether the electoral system is majoritarian or not. For unpublished papers, we included the year the paper was made available online.

# C Meta-Analysis Dataset

Our meta-analytic data is comprised of two datasets. The first dataset has the main coefficients reported in the studies. These data include only the most rigorous model from each paper, that is, those estimated with the largest n, most control variables, and fixed effects if the authors added them. If the article employed a regression discontinuity design, we chose the coefficient from the optimal bandwidth or from the intermediate one. This sample encompasses 36 estimates, as 10 articles analysed two dependent or independent variables of interest. Our second sample, in contrast, contains all the 126 effect sizes reported in the 26 papers.

In the main text, we focus on the results for our restricted sample as we consider them more robust, but the findings are very similar when we use the extended set. Below is the data extraction process for all relevant coefficients in the selected articles. Here we present the results of all tests performed in both reduced and full samples.

# D Descriptive Statistics

In this section, we show the descriptive statistics for our study sample. We focus on the following paper characteristics: study year, whether the paper has been published or not, the electoral system of the country discussed in the original study, the data aggregation level, as well as the distribution of the dependent and independent variables of interest. We also add a descriptive statistics table similar to the one in the main paper.

## D.1 Study Year

For study year, we have an average of 2009.33, with standard deviation of 6.5. The oldest study included in the paper is dated from 1998, while the most recent paper is dated from 2019. Therefore, we cover 21 years of tests of the *law of 1/n*.

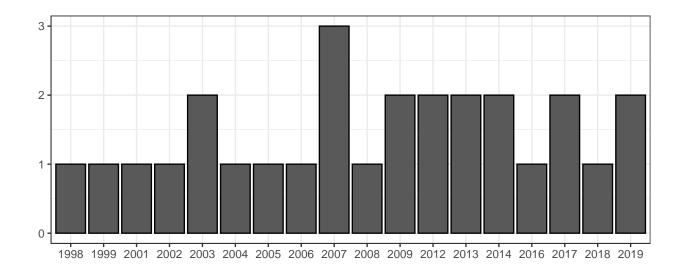

Figure 1: Study Year Frequencies

## D.2 Frequency of Published Papers

Studies were included in our sample regardless of their publication status. From the 26 papers in the sample, 22 were published while 4 were not published.

```
dat %>%
  select(id, published) %>%
  unique() %>%
  ggplot(aes(x = as.factor(published))) +
```

```
geom_bar(color = "black") +
labs(x = "Published Study?",
    y = "") +
theme_bw()
```

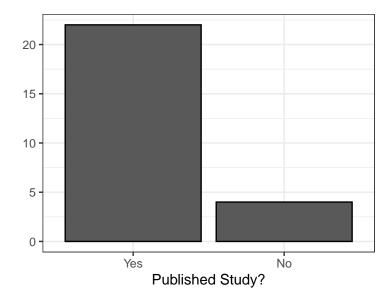

Figure 2: Was the study published?

#### **D.3** Electoral System

Our study selection differs considerably in regards to research design. One remarkable difference is that several authors apply the logics of the *law of 1/n*, which was built with majoritarian systems in mind, to non-majoritarian democracies. In our sample, 12 of the papers study *Majoritarian* systems while 14 study *Non-Majoritarian* electoral systems.<sup>3</sup>

```
dat %>%
  select(id, elecsys2) %>%
  unique() %>%
  ggplot(aes(x=as.factor(elecsys2))) +
    geom_bar(color = "black") +
  labs(x = "Electoral Systems",
    y = "") +
  theme_bw()
```

<sup>&</sup>lt;sup>3</sup>Note that the argument for working in a non-majoritarian system, we need to assume that despite the fact that politicians are able to campaign in every place in the district, the votes are geographically concentrated. The concentration facilitates politicians to use pork-barrel projects to captivate their electoral supporters.

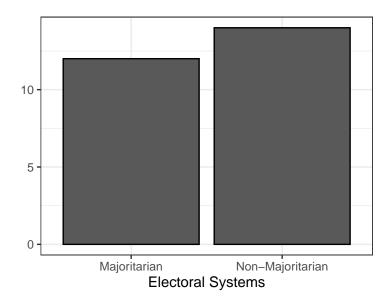

Figure 3: Electoral Systems

# **D.4** Dependent Variables

The outcome variables included in the paper are:

- 13 Per Capita Expenditure papers
- 7 Natural Log of Per Capita Expenditure papers
- 8 Expenditure as a Percentage of the GDP papers

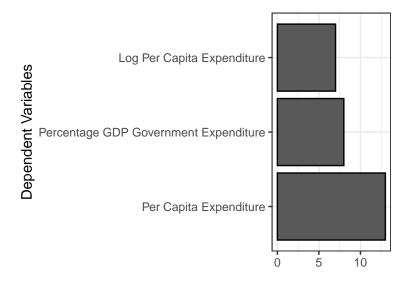

Figure 4: Dependent variables across the law of 1/n studies

#### **D.5** Independent Variables

Most of papers in our sample analyse the number of legislators in the lower house (20). The second most frequent independent variable is the number of legislators in the upper house (9). Finally, the minority of papers use the natural log of the number of legislators in the lower house as an independent variable (5). As we noted above, some papers had multiple coefficients, and thus the total number of coefficients is 36, while the number of papers is only 26.

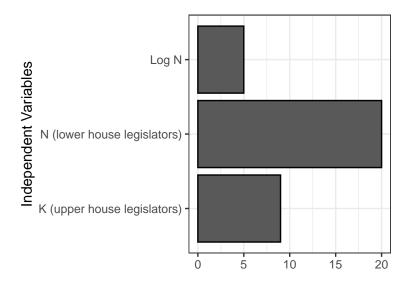

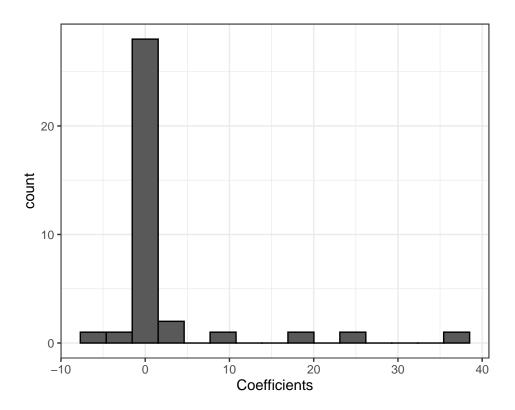

Figure 5: Independent variables across the law of 1/n studies

# D.6 Histogram of the Coefficients and the Standard Errors

The coefficients in the papers present a striking variability. In this section, we plot a histogram of the coefficients for all measurements included in the meta-analytic dataset.

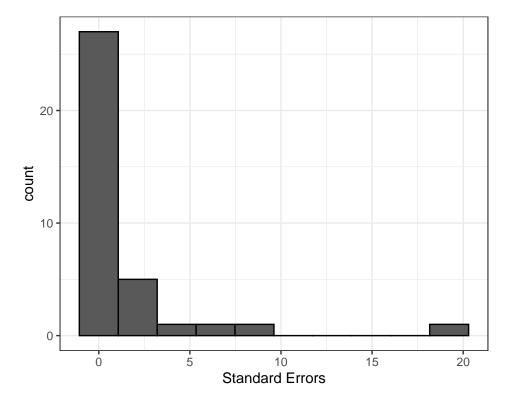

Coefficients:

```
dat %>%
  ggplot(aes(x = coef)) +
  geom_histogram(bins = 15, color = "black") +
  labs(x = "Coefficients") +
  theme_bw()
```

# Standard errors:

```
dat %>%
  ggplot(aes(x = SE)) +
  geom_histogram(bins = 10, color = "black") +
  labs(x = "Standard Errors") +
  theme_bw()
```

# **D.7** Sign Coefficients

One simple statistic that we can compute to assess the validity of the *law of 1/n* is the frequency of positive and negative estimates in the study sample. Below we plot the frequency for all the papers included in the meta-analytic dataset.

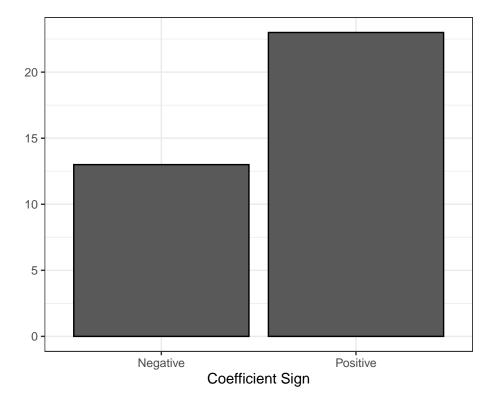

Figure 6: Coefficient Sign

# **E** Descriptive Statistics of Moderators

We chose a set of moderators that frequently appear in the literature and may help us interpret our results. We included them in our meta-regressions alongside an indicator for the type of independent variable used in the original study  $(n, \log(n), \text{ or } k)$ . The additional moderators are: 1) electoral system; 2) data aggregation level; 3) estimation method; 4) publication year; 5) paper publication in an academic journal. The table below presents descriptive statistics for these moderators in our selection of articles.

```
levels(fulldat$usemeta2) <- c("Other Coefficients", "Main Coefficients")</pre>
aux <- select(fulldat, usemeta2, indepvar2, year, published,</pre>
            elecsys2, method) %>%
 rename(`Independent Variables` = indepvar2,
        `Year` = year,
        `Published work` = published,
        `Electoral system` = elecsys2,
        `Estimation method` = method)
descrTable(~.-usemeta2, aux, y = aux$usemeta2,
    show.p.overall = F, show.all = T)
##

# F Binomial Tests for Coefficient Signs

The *law of 1/n* posits that we should expect a positive influence of legislature size on public expenditures. A general test of the theory could investigate whether the papers tend to find a higher frequency of positive coefficients in their estimations. In statistical terms, consider a random variable representing the coefficient sign for the papers. As each sign of the paper is a Bernoulli trial, the aggregate result for all papers follows a Binomial distribution with parameters n equals the number of papers, and p the chance of a positive sign. The *law of 1/n* can be reformulated as the chance of p > 0.5, which facilitates the testing of the theory. The null hypothesis for such a test is that:

•  $H_0$ : the proportion of positive and negative signs are indistinguishable (p = 0.5).

As we are taking an agnostic approach, we acknowledge that either the *law of 1/n* (p > 0.5), or the *reverse law of 1/n* (p < 0.5) could be true. In this case, the alternative hypothesis is  $p \neq 0.5$ . To perform this test, we run binomial tests in R, using the function binom.test(.).

This test has two advantages. First, it is robust to the design of the paper. This is an important feature as papers analyse different countries, samples, and have distinct characteristics, such as whether they were published or not. All these factors increase the levels of study heterogeneity. The binomial test ignores the design discrepancies and focuses on the overall reported effect. Second, this test has the advantage of being straightforward and easy to interpret. It requires very few assumption and has a direct statistical formulation. The disadvantage is that we can extract more information from the articles with meta-regressions, as we see in the next sections.

For the number of legislators in the lower house (N), the results follow below.

```
aux <- filter(dat, indepvar2 == "N")
aux2 <- binom.test(table(aux$scoef)[2], sum(table(aux$scoef)), p = 0.5)
aux2

##
## Exact binomial test
##
## data: table(aux$scoef)[2] and sum(table(aux$scoef))</pre>
```

```
## number of successes = 10, number of

## trials = 21, p-value = 1

## alternative hypothesis: true probability of success is not equal to 0.5

## 95 percent confidence interval:

## 0.2571306 0.7021932

## sample estimates:

## probability of success

## 0.4761905
```

Under the null hypothesis of p=0.5, we find that 10 studies, out of 21, had positive sign. The chance of a distribution with p=0.5 generate this sample is equal to p-value = 1. Therefore, we reject the hypothesis that  $p \neq 0.5$ .

For the log of the number of legislators in the lower house  $(\log(N))$ , the results follow below.

```
aux <- filter(dat, indepvar2 == "logN")</pre>
aux2 <- binom.test(table(aux$scoef)[2], sum(table(aux$scoef)), p = 0.5)</pre>
aux2
##
    Exact binomial test
##
## data: table(aux$scoef)[2] and sum(table(aux$scoef))
## number of successes = 5, number of
## trials = 6, p-value = 0.2188
## alternative hypothesis: true probability of success is not equal to 0.5
## 95 percent confidence interval:
   0.3587654 0.9957893
## sample estimates:
## probability of success
                0.8333333
##
```

Under the null hypothesis of p = 0.5, we find that 5 studies, out of 6, had positive sign. The chance of a distribution with p = 0.5 generate this sample is equal to p-value = 0.219. Therefore, we reject the hypothesis that  $p \neq 0.5$ .

Finally, for the number of legislators in the upper house (*K*), the results follow below.

```
aux <- filter(dat, indepvar2=='K')
aux2 <- binom.test(table(aux$scoef)[2], sum(table(aux$scoef)), p=0.5)
aux2

##
## Exact binomial test
##
## data: table(aux$scoef)[2] and sum(table(aux$scoef))
## number of successes = 8, number of
## trials = 9, p-value = 0.03906
## alternative hypothesis: true probability of success is not equal to 0.5
## 95 percent confidence interval:
## 0.5175035 0.9971909
## sample estimates:
## probability of success</pre>
```

Under the null hypothesis of p = 0.5, we find that 8 studies, out of 9, had positive sign. The chance of a distribution with p = 0.5 generate this sample is equal to p-value = 0.039. Therefore, we accept the hypothesis that  $p \neq 0.5$ . This is the only test that presents evidence of an association between the legislature size and expenditure.

# **G** Meta-Analysis

##

#### **G.1** Estimation Method

0.8888889

In general terms, there are two main ways to conduct a meta-analysis, either using fixed effects or random effects models. The fixed effects model assumes that there is one true effect in reality, and that all estimates are an attempt to uncover this true, unknown effect. The random effects model, on the other hand, assumes that there is a distribution of true effects, one which varies based on sample and tests characteristics.

In this paper, we use the random effects model. We do so because the empirical papers testing the law of 1/n are very diverse. We tried to capture some of this diversity by considering the main dependent and independent variables separately, but they have at least three other important sources of dispersion:

- 1. Subjects: Counties, Municipalities, States, Provinces, Countries.
- 2. Electoral systems: Majoritarian, PR, Mixed.

#### 3. Modelling strategies: Panel data, Standard OLS, IV, RDD.

These sources of heterogeneity have two implications. First, they make our estimates very disperse. All but one of our heterogeneity tests are statistically significant. When the sample sizes were large enough, we removed more heterogeneous studies, but we still had considerable dispersion in our estimates. Second, the amount of heterogeneity makes fixed effects estimates unrealistic and biased. Thus, we opt for random effects model.

Let each study having an effect of  $T_i$ . In a random effects model, we can decompose this effect in two components, the true effect that the study with the same specifications as i comes from,  $\theta_i$ , and a within-study error  $\varepsilon_i$ :

$$T_i = \theta_i + \varepsilon_i$$

And the random effects model assumes that the  $\theta_i$  varies from study to study, having a true parameter  $\mu$ , plus a between-study error,  $\xi_i$ :

$$T_i = \mu + \xi_i + \varepsilon_i$$

And the random effects model estimates the parameter  $\mu$ , under the challenge of estimating both the within-and-between-study sampling errors.

In all empirical estimates, we use the package meta, and the package dmetar, described in Doing Meta-Analysis with R. To empirically implement the random effects model, we need to choose a method to estimate the true effect size variance,  $\tau^2$ , which in our formulation, represents the variance of  $\xi_i$ . We selected the **Restricted Maximum Likelihood Estimator**, as the literature regards it the most precise when analysing continuous measures, such as we have in our data.

We combined the three independent variables (N,  $\log(N)$ , and K) with our dependent variables of interest (Expenditure Per Capita, Log of Expenditure Per Capita, Expenditure as a Percentage of the GDP). This formed a  $3 \times 3$  table, and in the following pages we present the results for each of these combinations.

#### G.2 Lower House Size and Expenditure per Capita

#### build\_forest(mod, NULL)

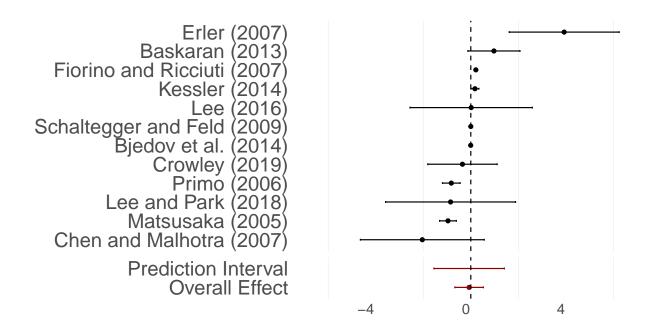

Figure 7: Effect of lower houses size (N) on Per Capita Expenditure (ExpPC)

## Highlights:

- 1. The results are highly heterogeneous:  $I^2 = 94.68$ .
- 2. The estimated SMD in the random effects model is q = -0.07 (SE = 0.273).
- 3. The prediction interval ranges from -1.55 to 1.41. Therefore, it emcompasses zero.

#### **G.2.1** Electoral System Subgroup Analysis

The *law of 1/n* was created for majoritarian systems. In the theoretical section below, we explain why the argument have potential issues when applied to non-majoritarian electoral systems. We estimated a subgroup

analysis using a binary electoral system.

```
mod <- update(mod, byvar = aux$elecsys2, print.byvar = F)</pre>
mod2 <- tibble(</pre>
 TE = mod\$TE,
  seTE = mod$seTE,
  studlab = mod$studlab,
  lower = mod$lower,
  upper = mod$upper,
  group = "A") %>%
  bind_rows(.,
            aux = tibble(
              TE = c(mod$TE.random, NA),
              seTE = c(mod$seTE.random, NA),
              studlab = c("Overall Effect", "Prediction Interval"),
              lower = c(mod$lower.random, mod$lower.predict),
              upper = c(mod$upper.random, mod$upper.predict),
              group = "B")) %>%
  group_by(studlab) %>%
  mutate(studlab2 = paste0(studlab, "_", 1:n())) %>%
  ungroup()
f1b <- mod2 %>%
  ggplot(aes(y = reorder(studlab2,TE), x = TE, xmin = lower, xmax = upper)) +
  # Studies coefs
  geom_point(aes(color = group)) +
  geom_errorbarh(aes(color = group), height = 0.1) +
  # Colors
  scale_color_manual(values = c("#000000", "#8b0000")) +
  # X-axis limit
  scale_x_continuous(limits=c(1.2*(min(mod2$lower)), 1.2*(max(mod2$upper)))) +
```

```
# Y-axis names
  scale_y_discrete(labels = function(x) str_replace(x, "_[0-9]*$", "")) +
  # Vertical dashed line
  geom_vline(xintercept=0, color="#000000", linetype="dashed") +
  # Labels
 labs(x = "",
      y = "") +
  # Facet - Separating Studies from Overall Effect
  facet_grid(group~., scales = "free", space = "free") +
  # Theme
  theme_minimal() %+replace%
  theme(strip.text.y = element_blank(),
       legend.position = "none",
       axis.text.y = element_text(size = 15, hjust = 1.1),
        axis.text.x = element_text(size = 15, hjust = 1.1))
f1b
```

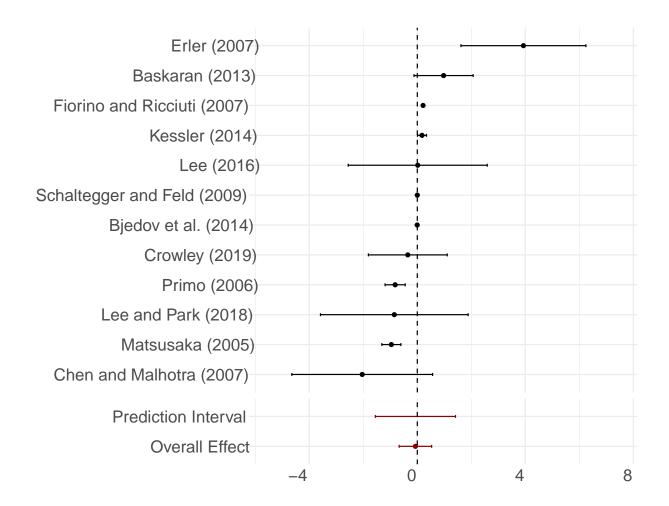

Figure 8: Subgroup Analysis of (N) x (ExpPC), controlling by electoral system

Therefore, we can see that the hypothesis that majoritarian systems produce systematic positive effects was disproved. The majoritarian systems in the sample had a random effects model estimate of -0.25, while the random effects model in the non-majoritarian subgroup fitted a value of 0.08. Both are non-significant, but they reassure us that the absense of effect is not caused by pooling multiple types of electoral systems.

#### G.3 Log Lower House Size and Expenditure per Capita

There were no studies that had per capita expenditure in the dependent variable and log of lower house size in the treatment variable.

#### G.4 Upper House Size and Expenditure per Capita

Now, we look into the upper house size (K). In this model, we investigate the effect of upper house size on expenditure per capita (ExpPC).

```

The forest plot is available below:

build\_forest(mod, NULL)

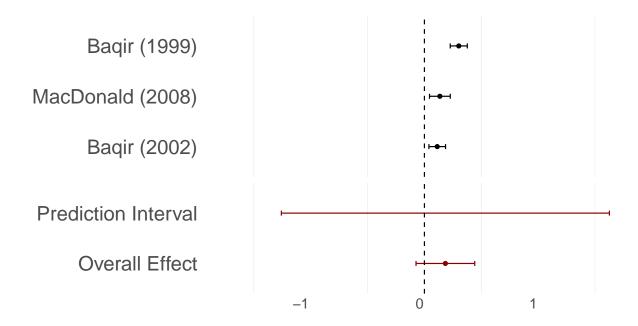

Figure 11: Effect of log lower houses size (logN) on the log of per capita government expenditure (logExpPC)

Highlights:

- 1. The results are highly heterogeneous:  $I^2 = 85.9$ .
- 2. The estimated SMD in the random effects model is g = 0.18 (SE = 0.06). This model is significant at the 10% confidence level.
- 3. The prediction interval ranges from -1.26 to 1.63. Therefore, it emcompasses zero.

# G.7 Log of Upper House Size and Log of Expenditure Per Capita

No studies related the log of per capita expenditure with the size of upper house (K).

#### G.8 Lower House Size and Expenditure as Percentage of GDP

This model fits the random effects for the percentage of GDP as public expenditure as the main outcome, and the size of lower house as the main treatment variable.

   The forest plot:
```

build\_forest(mod, NULL)

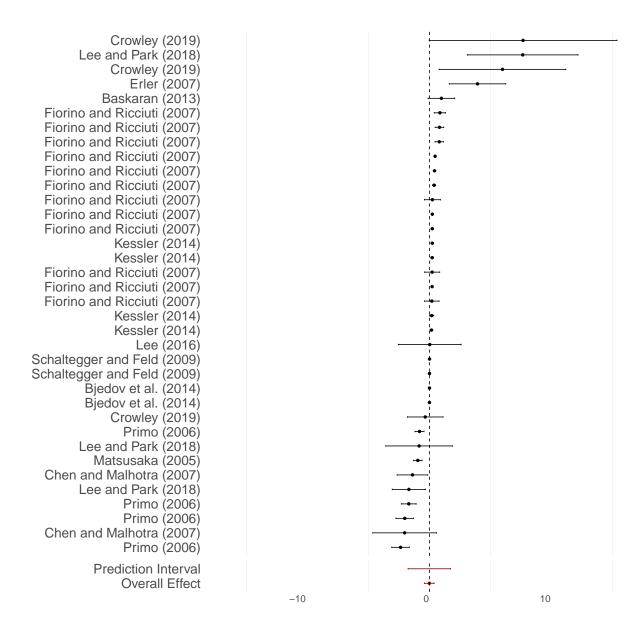

Figure 15: Effect of Lower House Size (N) on Per Capita Expenditure (ExpPC)

- 1. The results are highly heterogeneous:  $I^2 = 95.27$ .
- 2. The estimated SMD in the random effects model is q = -0.02 (SE = 0.197).
- 3. The prediction interval ranges from -1.76 to 1.73. Therefore, it emcompasses zero.

#### **H.1.1** Electoral System Subgroup Analysis

The *law of 1/n* was created for majoritarian systems. In the theoretical section below, we explain why the argument have potential issues when applied to non-majoritarian electoral systems. We estimated a subgroup analysis using a binary electoral system.

```
mod2 <- tibble(</pre>
  TE = mod\$TE,
  seTE = mod$seTE,
  studlab = mod$studlab,
  lower = mod$lower,
  upper = mod$upper,
  group = "A") %>%
  bind_rows(.,
            aux = tibble(
              TE = c(mod$TE.random, NA),
              seTE = c(mod$seTE.random, NA),
              studlab = c("Overall Effect", "Prediction Interval"),
              lower = c(mod$lower.random, mod$lower.predict),
              upper = c(mod$upper.random, mod$upper.predict),
              group = "B")) %>%
  group_by(studlab) %>%
  mutate(studlab2 = paste0(studlab, "_", 1:n())) %>%
  ungroup()
f8b <- mod2 %>%
  ggplot(aes(y = reorder(studlab2,TE), x = TE, xmin = lower, xmax = upper)) +
  # Studies coefs
  geom_point(aes(color = group)) +
  # Error Bars
  geom_errorbarh(aes(color = group), height = 0.1) +
  # Colors
  scale_color_manual(values = c("#000000", "#8b0000")) +
  # X-axis limit
  scale_x_continuous(limits=c(1.2*(min(mod2$lower)), 1.2*(max(mod2$upper)))) +
  # Y-axis names
  scale_y_discrete(labels = function(x) str_replace(x, "_[0-9]*$", "")) +
  # Vertical dashed line
  geom_vline(xintercept=0, color="#000000", linetype="dashed") +
```

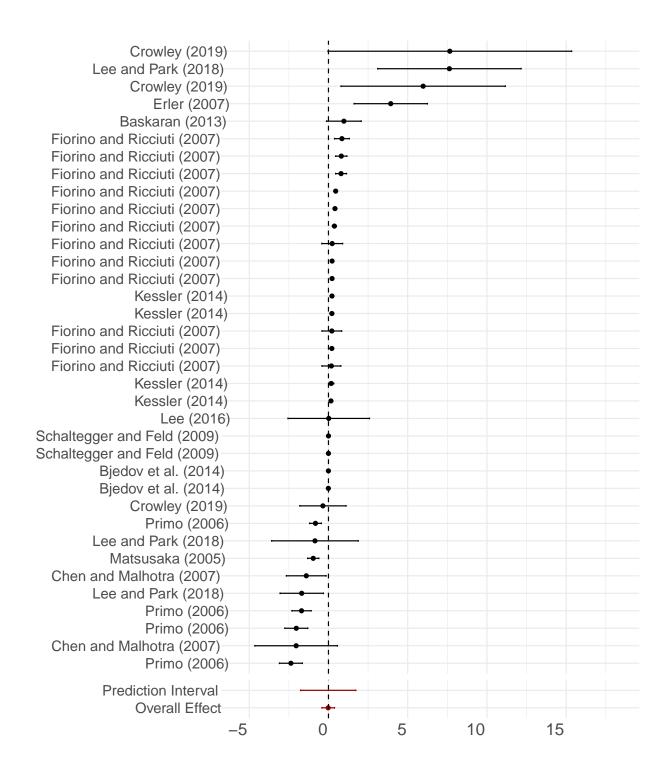

Figure 16: Subgroup Analysis of (N) x (ExpPC), controlling by electoral system

Therefore, we can see that the hypothesis that majoritarian systems produce systematic positive effects was disproved. The majoritarian systems in the sample had a random effects model estimate of -0.25, while the random effects model in the non-majoritarian subgroup fitted a value of 0.08. Both are non-significant, but they reassure us that the absence of effect is not caused by pooling multiple types of electoral systems.

#### H.2 Log of Lower House Size and Expenditure Per Capita

There were no studies that had per capita expenditure in the dependent variable and log of lower house size in the treatment variable.

## H.3 Upper House Size and Expenditure Per Capita

Now we investigate the effect of the upper house size (K) on government spending. In the model below, we evaluate the relationship between upper house size and expenditure per capita (ExpPC).

```

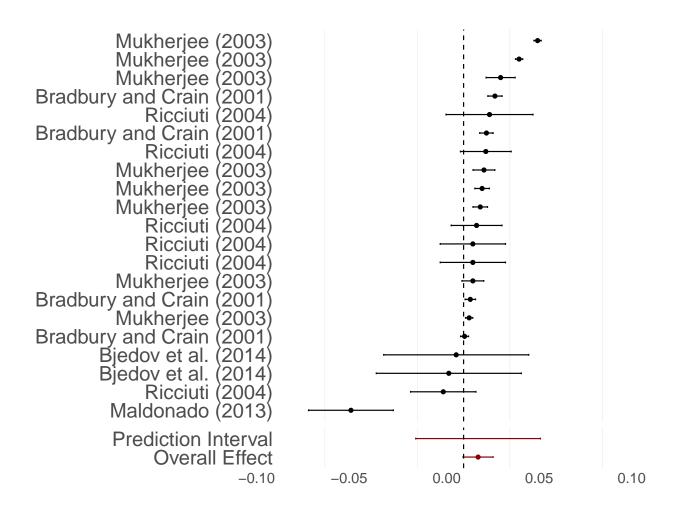

Figure 20: Effect of lower houses size (N) on percentage of public expenditure GDP (PCTGDP)

- 1. The results are highly heterogeneous:  $I^2 = 98.48$ .
- 2. The estimated SMD in the random effects model is q = 0.01 (SE = 0.004).
- 3. The prediction interval ranges from -0.03 to 0.04. Therefore, it emcompasses zero.

### H.8 Log of Lower House Size and Expenditure as Percentage of GDP

This meta-regression investigates the percentage of GDP as public expenditure as the dependent variable and the natural logarithm of lower house size  $(\log(N))$  as the treatment variable.

```
# Pooling effects analysis -- PCTGDP x logN

aux <- fulldat %>%

filter(indepvar2 == 'logN',
```

```

  model = "PCTGDP - Permutation"
) %>%
  mutate_if(is.numeric, list(~round(., digits = 3)))
```

We have the following results for the meta-regressions of Expenditure as a Percentage of GDP:

- 1. Compared with K, models with N and logN find significantly negative coefficients.
- 2. Year has null effect.
- 3. Unpublished papers tend to have higher coefficients than published papers.
- 4. Passing from Majoritarian to Non-Majoritarian, decreases significantly the effects found in our models.
- 5. In terms of modelling, passing from OLS to PANEL increases the detected effects.
- 6. When passing from Country to Cross-Country, it has no effect on the estimated coefficients.

Below we also run the meta-regressions adding all coefficients in the papers. The results follow below:

```
mods = ~ indepvar2+year+published+elecsys2+method,
              test = "knha",
            subset = fulldat$depvar2=='PCTGDP',

         "Method: Panel",
         "Method: IV"),
 Estimate = mod[["beta"]],
 SE = mod[["se"]],
```

We have the following results for the meta-regressions of Expenditure Per Capita:

- 1. Compared with K, models with N tend to detect significantly smaller effects.
- 2. Year has null effect.
- 3. Majoritarian, when compared to Non-Majoritarian electoral systems, significantly increase per capita expenditure.
- 4. In terms of the modeling, passing from OLS to PANEL or IV increases the detected effects.

We also run the meta-regressions adding all coefficients in the papers. The results follow below:

```
mod <- rma(yi = coef,</pre>
              sei = SE,
              data = fulldat,
              method = "REML",
              mods = ~ indepvar2+year+published+elecsys2+method,
              test = "knha",
            subset = fulldat$depvar2=='ExpPC',
            slab = fulldat$authoryear)
mod4 <- tibble(</pre>
  ` = c("Intercept",
          "Indepvar: N",
          "Year",
          "Elecsys: Non-Majoritarian",
          "Method: Panel",
          "Method: IV"),
  Estimate = mod[["beta"]],
```

```

With all coefficients, the results of the effect sizes on the Expenditure Per Capita regressions are the following:

- 1. Compared with K, models with N tend to detect significantly smaller effects.
- 2. Year has now a positive effect on coefficient sizes.
- 3. Majoritarian, when compared to Non-Majoritarian electoral systems, significantly increase per capita expenditure.
- 4. In terms of the modeling, passing from OLS to PANEL decreases the detected effects.
- 5. All other coefficents were not significant.

We have the following results for the meta-regressions of Log of Expenditure Per Capita:

- 1. Unpublished papers report significantly higher coefficients.
- 2. In terms of the modeling, passing from OLS to PANEL increases the detected effects.
- 3. All other coefficients remained insignificant.

Below we also run the meta-regressions adding all coefficients in the papers. The results follow below:

```
mod <- rma(yi = coef,</pre>
              sei = SE,

# J Robustness: Full Model Meta-Regressions Combined

In this section, we aggregate all the coefficients and run a multivariate meta-regression, controlling for:

- 1. The type of the dependent variable in the study (expenditure per capita, log of the expenditure per capita, and share of government expenditure in the GDP)
- 2. The type of the independent variable in the study (N, K, log(N));
- 3. The electoral system (Majoritarian, Proportional Representation, and Mixed).

The results follow below, and show null effects for all variables, including the intercept.

```
mods = ~ depvar2+indepvar2+year+published+elecsys2+method,

test = "knha")
```

```
